

Supplementary Figure 4: Eyes without signs of venous overload but with choroidal hyperpermeability. Ultra-widefield (UWF) fundus fluorescein angiography (A, D, G), early-phase UWF indocyanine green angiography (ICGA), and late-phase UWF ICGA of three eyes that showed FFA appearance typical of CSC, but no significant signs of venous overload on mid-phase UWF ICGA. All eyes showed multiple areas of choroidal hyperpermeability on late-phase UWF ICGA, again highlighting its diagnostic specificity.
